Dianabol (Dbol) is one of the rare steroids that was originally created to enhance the athletic performance of steroid users, rather than being developed for other purposes such as treating medical conditions or use in animals. It provides major muscle and strength gains by increasing nitrogen retention and working out quickly, making it a key compound in most advanced stacks. Dianabol has a lower androgenic nature compared to testosterone due to a slight change in the chemical structure of the hormone, but still retains its highly anabolic effect. The main benefits of this very powerful steroid relate to the key areas that affect muscle development: Increasing protein synthesis – This rapidly increases the protein-making process in cells, the building blocks of muscle growth. Increasing nitrogen retention – maintaining a positive nitrogen balance ensures that the body remains in a primary anabolic state. Enhanced glycogenolysis – conversion of carbohydrate glycogen in liver and muscle cells into glucose for use as energy. These basic but most critical processes of the body contribute to the overall extremely powerful anabolic effects of Dianabol. Due to its ability to provide tremendous bulking and strength gains, Dianabol is mostly used by bodybuilders for these purposes. It is rarely used for cutting, except for very experienced or professional steroid users with a specific purpose, because there are better cutting steroids on the market.
