Methyltestosterone is an androgen receptor agonist. Methyltestosterone is a testosterone mimetic used in the treatment of men with testosterone deficiency and related androgen replacement therapies. Additionally, it is used as an antineoplastic agent in the treatment of breast cancer in postmenopausal women. Methyltestosterone is a derivative of testosterone that carries a methyl group at position 17 alpha, which functionally increases bioavailability. Methyltestosterone binds to cytosolic androgen receptors, and the ligand-receptor complex functions as a transcription factor that regulates the expression of androgen-responsive genes. Androgen-responsive genes are responsible for the growth and development of male sex organs and male secondary sexual characteristics. Anabolic agents such as methyltestosterone stimulate anabolism and inhibit catabolism, thereby stimulating the development of muscle mass, strength and power.
